Abstract
Purpose – This paper explores the link between value co-creation, a project’s success and satisfaction of the project’s stakeholders. It also looks at how a project’s success mediates the relationship between value co-creation and the stakeholder’s satisfaction.

Design/methodology/approach – A quantitative approach with an online questionnaire was used to collect data from a sample of 140 respondents in Ghana. Data were analyzed using Partial Least Square Structural Equation Modelling (PLS-SEM).

Findings - The results show that value co-creation positively and significantly relates to a project’s success and stakeholder satisfaction. The findings also support that a project’s success mediates the impact of value co-creation on the stakeholders’ satisfaction. Based on these findings, we suggest that project managers be critical about the type of value co-creation strategy they will use to engage project stakeholders. This would apply when adopting the value co-creation approach to manage their projects while not sacrificing success.

Research limitations/implications - This study focused on the impact of value co-creation on a project’s success and its stakeholder’s satisfaction. The survey data were collected only to evaluate the overall effect of value-co-creation on the success and stakeholder’s satisfaction of projects.

Practical implications - The adoption and implementation of value co-creation in project management may enhance the definition of the project’s scope, performance specifications, and other criteria used to measure the success of a project, to meet the needs of stakeholders.

Originality/value - By empirically presenting a project’s success as a key mediator in shaping the effect of adopting value co-creation in project
management on the stakeholder’s satisfaction, this study laid a foundation for further theoretical explorations involving value co-creation in project management.

**Keywords:** Value Co-creation, Project Stakeholder Management, Project Success, Stakeholder Satisfaction, Project Management.

**INTRODUCTION**

The number of project failures recorded over past decades had exposed flaws in the conventional approaches to project management. These failures reflect the need for new and dynamic approaches, such as value co-creation (Cohen, Rozenes and Horowitz, 2017). The adoption of the value co-creation approach towards project management is highly recommended. This is due to the complexity, nonroutine and one-time effort of projects. In addition, projects are often limited by time, budget, resources, and performance specifications which are designed to meet customer needs.

Projects also require good collaboration, consistent relational engagement, and innovativeness across its lifespan (Rojas, Liu, & Lu, 2018; Chang et al., 2013; Matinheikki et al., 2015; Mele, 2011; Rod et al., 2014; Nord, 2012; Liu et al., 2014; Aarikka-Stenroos and Jaakkola, 2012; Jacobsson and Roth, 2014).

The major goal of a project is to satisfy the needs of all stakeholders involved in the project. Freeman (1984) defined stakeholders as “any group or individual who is affected by or can affect the achievement of an organization’s objective” (p. 4). A project’s stakeholders are individuals or organizations that may have either a positive or negative impact on the
project. The successful engagement and effective participations of stakeholders throughout a project’s life cycle are critical to its success.

Co-creation in projects encourages proactive engagement of a project’s stakeholders in different phases of the project's life cycle, contributing to its success (Gajic, Fajsi, Jovanovic, Moraca, and Lalic, 2014). Co-creation occurs through effective and consistent interactions between the project manager, project team and all possible stakeholders (Smyth, Lecoeuvre, and Vaesken, 2018). Cohen et al., (2016) added that value co-creation in a project environment is a collaborative design process of engaging project stakeholders throughout the project’s life cycle. The concept of value co-creation has been widely researched on across literature in the fields of management and marketing (e.g. Payne et al., 2008; Maglio and Spohrer, 2008; Edvardsson et al., 2011). Wei and Lam (2014) indicated that stakeholders must be involved throughout the project’s life cycle to facilitate its success and ensure stakeholder’s satisfaction.

In the project management context, the value co-creation approach is a new way of managing the project itself, its team, customers, sponsors, and all possible stakeholders (Cohen, Rozenes, and Horowitz, 2017). Value is a concept that is often understood in vague terms and is sometimes used interchangeably with words such as benefit, outcome, and worth, in project management research (Schryen, 2013; Zwikael and Smyrk, 2012). To understand value co-creation in construction projects, Fuentes and Smyth, (2016) and Haddadi et al., (2016) provided a framework that enables a
project to move the focus of enablers from the project’s perspective to a more prolonged perspective.

Alhava and Kiviniemi’s (2015) investigation of an intensive big room process for co-creating value in legacy construction projects, revealed that service logic and value co-creation are unique strategies in a standard contract-based environment. They provide significant benefits to companies that are able to adopt these concepts into their business models. Similarly, Smyth and Vaesken’s (2018) qualitative study on the co-creation of value in projects showed that decision-making extends beyond the time-cost-quality/scope dimensions. Studies on the use of co-creation in construction projects attest that “the quality and quantity of value co-creation in project management are determined by the relationships, interactions and collaborations between the stakeholders and the construction firm” (Liu et al., 2014).

However, value co-creation has not yet been thoroughly studied in the context of the management of construction projects (Keränen and Jalkala 2013; Liu et al., 2014; Fuentes and Smyth, 2016; Razmdoost and Smyth, 2016; Rojas, Liu, & Lu, 2018). According to Liu, Fellows, and Chan (2014), although there has been extensive research on ways to improve the performance of construction projects, there is still a dearth of research on the importance of the value co-creation process in project management. Similarly, most researches in the past on value co-creation focused on its value in routine services, which are unlike projects which are nonroutine and temporary endeavours (Keränen and Jalkala 2013; Razmdoost and Smyth, 2016).
Therefore, Fuentes and Smyth (2016) recommended that more research needs to be conducted on how value co-creation could improve the outcomes of construction projects. Likewise, Rojas, Liu, & Lu (2018) uncovered that value co-creation does not positively influence all types of projects, therefore, further investigation should be conducted on the impact of value co-creation on stakeholders, using data from a wider spectrum of project stakeholders within their population.

In addition, previous studies have either examined the relationships between value-co creation and a project’s success or value co-creation and project stakeholder satisfaction alone (see, Rojas et al., 2018; Keeys and Huemann, 2017). For instance, Rojas et al. (2018) examined value co-creation and a project’s success, while Keeys and Huemann (2017) investigated the effect of co-creation towards sustainable development of a project. The uniqueness of this research is to empirically examine value co-creation, a project’s success, and stakeholder’s satisfaction concurrently. This research highlights how the value co-creation approach in projects leads to success and satisfaction of stakeholders. The paper also examines the mediating effect of the project’s success towards the relationship between value co-creation and stakeholder satisfaction.
Value Co-creation in Project Management

Vargo and Lusch originally used the terms co-creation in 2004 (Vargo and Lusch, 2004) and later refined the concept in Vargo and Lusch (2014). Value is not static; it shifts based on past experiences, present realizations, and future anticipations (Grönroos and Voima, 2012). According to Roser et al. (2013, p. 4) “co-creation is an interactive, creative, and social process between stakeholders that is initiated by the firm” (i.e. service provider). Vargo and Lusch (2016) indicate that value co-creation is where organizations and individuals/stakeholders are interdependent in creating value for customers.

Studies have shown value is co-created when organizations practice stakeholder engagement, co-production, self-service, improving customer experience, problem-solving, dialogue, co-designing and co-developing firm products and services (Alexander and Jaakkola, 2016; Gebauer et al., 2010). In other words, value is jointly created by stakeholders and firms (Vargo and Lusch, 2016). Furthermore, because stakeholders co-create the end product with the organization, they would feel responsible for and be more satisfied with the outcome.

In examining co-value creation in project management, Fuentes and Smyth (2016) argued that co-creation of value needs to be managed before a service is in use. This notion however is in contrary to current trends reported in the marketing literature. Haddadi et al., (2016) proposed a method that helps
understand the user’s strategic objectives and used this knowledge to optimize the design of buildings, to enhance the value creation of the building projects. Their study revealed that value in a project’s life cycle is achieved when the needs and goals of the project are achieved. Smyth et al., (2018) applied Service-dominant logic (SDL) to analyze a megaproject as a single case study in a nuclear power station in the UK. Their findings revealed that matters relating to value are often overlooked; instead, stakeholders and individual actors focused upon managing political and financial risks, especially time and cost.

**Table 1:** Summary of related literature on value co-creation in the management of various projects

The literature review above indicates that little empirical work focused on value co-creation in project management. The present study specifically and concurrently examines value co-creation, the project’s success, and its stakeholder’s satisfaction. Thus, this research may contribute to the literature on project management.
HYPOTHESES

Value Co-Creation and Project’s Success

Projects are designed and constructed to meet the needs and expectations of a wide variety of project participants and stakeholders. However, multiple stakeholders with different interests, expectations and influences, makes it very challenging to determine the success of a project. Although there has been much discussion on the nature and definition of a project’s success, no consensus has emerged (Bannerman, 2008). Nevertheless, there is also a lack of common criteria which can be used to measure a project’s success in the context of project management. The success of every project is determined by what is called the triple bottom constraints, which is to complete a project within the bounds of the most immediate design parameters (time, cost, and scope). This meant that a successful project is one that is on time, on budget, and within the design scope.

According to Bannerman (2008), a project’s success variously refers to completion which is “on time, within budget, [and] to specification”; the success of the product produced; or success in achieving the business objectives of the project. Rojas, Liu, and Lu (2018) conducted a study on the moderated effect of value co-creation on a project’s performance using data from a cross-sectional survey of 120 Chilean construction project managers. The study concluded that value co-creation relates significantly and positively to a project’s success and performance. Similarly, the results of Corsaro (2018) revealed that the value co-creation process positively
influences the success of a project. The results further pointed out that the management of value co-creation implies the consideration of complex interconnecting patterns with other value processes.

Savolainen, Saari, Männistö, and Kähkonen (2018) researched on indicators of collaborative design management in construction projects using a quantitative user satisfaction survey. The study also employed a qualitative analysis of the documentations from the case project, as a form of strategized data collection. The analysis revealed a significant positive relationship between value co-creation and the project’s quality performance. This would reflect that when project stakeholders are involved in value co-creation, the chances of the project to be successful are very high.

Therefore, it is hypothesized that:

**H1:** Value co-creation is positively related to the success of construction projects.

**Value Co-Creation and Stakeholders’ Satisfaction**

Customer satisfaction equates to how products and services from a firm meet the customer’s expectations (Kim *et al.*, 2013). Customer satisfaction is evoked by the customer’s experience with a particular company (Terpstra and Verbeeten, 2014). Additionally, the satisfaction of project stakeholders has become a prominent criterion to measure a project’s success, in addition
to the traditional determinants of cost, quality, and time (Davis, 2016). Stakeholder’s satisfaction in construction projects is difficult to measure since individual stakeholders have different views on when a project is considered a success.

The Savolainen, Saari, Männistö, and Kähkonen (2018) study revealed that a high level of quality in customer satisfaction is attained when construction firms or project-based firms practice value co-creation involving stakeholders. McHugh, Domegan, and Duane (2018) agrees with Savolainen et al. (2018) that value co-creation with stakeholders improves their satisfaction towards the project. Both studies further revealed that co-creating value “with” stakeholders rather than “on” their behalf can build bridges and transform societies. Similarly, Sahi, Sehgal, and Sharma (2017) revealed that value co-creation is a platform where customers should proactively participate. Architects are able to promote this proactiveness by acknowledging the customer’s ideas and suggestions, and this have resulted in a significant positive impact on customer’s satisfaction.

It was also found that a project’s customers and other stakeholders usually recommend and promote a construction firm to others through a positive word-of-mouth when they are allowed to participate in value creation (Sahi, Sehgal, and Sharma, 2017). In support to the work by Sahi et al (2017), Firend and Langroudi (2016) reported that value co-creation activities have a positive impact on consumer satisfaction in the Southeast Asian manufacturing sector. According to Grisseman and Stokburger (2012), the
degree of which the stakeholders are involved in value co-creation positively influences their satisfaction towards the firm, as well as that of the customer’s. Therefore, it is hypothesized that:

**H2**: Value co-creation is positively related to a construction project’s stakeholder’s satisfaction.

**Mediation Effect of Project’s Success in the Relationship Between Value Co-creation and Stakeholder’s Satisfaction**

Research has also shown that there is an indirect relationship between value co-creation and stakeholder’s satisfaction in the marketing, management, and project management literature. Markovic and Bagherzadeh (2018) in their study conducted on 1516 Spanish firms, concluded that the breadth of external stakeholder co-creation is not directly related to the innovation’s performance but rather knowledge sharing, followed by product innovation. The findings of Keeys and Huemann (2017) demonstrated that value co-creation with stakeholders enables the sustainable development of a project, which in turn creates stakeholder’s satisfaction. Implementing value co-creation will help decision-makers to move their focus from what is best for the project to what is best for the users, the owner and all other possible stakeholders of the project (Haddadi, Johansen, and Andersen, 2016). Therefore, it is hypothesized that:

**H3**: Success of a project will mediate the relationship between value
co-creation and stakeholder’s satisfaction.

The aforementioned discussion can be summarized in a conceptual model depicted in Figure 1.

![Diagram showing relationships between value co-creation, project success, and stakeholder’s satisfaction](image)

**Figure 1**: Relationships between value co-creation, project success, and stakeholder’s satisfaction

**RESEARCH METHODOLOGY**

This research adopted a quantitative approach to address the research problem. Sekaran and Bougie (2013) emphasized that the quantitative approach requires the research to be consistent with a positivist philosophy. The justification for using this research paradigm to test the relationship between value co-creation, project success, and project stakeholder satisfaction is its frequent use in recent studies on the co-creation of value in project management (see, Rojas, Liu, and Lu, 2018; Savolainen, Saari,
Sampling and Data Collection

This study employs a correlational design to examine the relationships between value co-creation, project success, and stakeholder’s satisfaction. Correlational research is a type of non-experimental measurement of two variables and assesses the statistical relationship between them with little or no effort to control extraneous variables. To examine the conceptual model generated and test these relationships, an online survey instrument was designed and measurement scales were developed. The draft questionnaire was constructed and validity of the scales checked and improved. A revised questionnaire was finalized and used to collect data via the Kwiksurveys platform (https://kwiksurveys.com/s/WZdiMcAi). To test the study’s hypotheses, data were collected from a sample of 140 project directors, managers, contractors, consultants, engineers, leaders, and team members in Ghana through the online survey questionnaire. The questions on the questionnaire were structured using the 7-point Likert scale format (7= Completely Agree and 1= Completely Disagree).

Analysis of the demographic data revealed that 62.9% of the respondents were male and 37.1% were female. We also found that the majority (42.9%) of the respondents were 30-35 years old, followed by the 25-29 age group which represented 40% of total respondents. Also, a significant 78.6% of the
respondents are first-degree holders while 20% and 1.4% of them, respectively, have a master's and doctorate degree as their higher education. The results showed that 51.4% of the respondents have been involved in building construction projects, 24.3% took part in road construction projects, and the remaining 24.3% previously worked in other kinds of construction projects. The respondents who participated in the study consisted of 14.3% project managers and directors, 11.4% project contractors, 4.3% project consultants, 31.4% project leaders, 34.3% project team members, and 4.3% project engineers. Additionally, 55.7% of the respondents indicated that they have had training in project management. Finally, 61.4% of the total respondents revealed that they have 2-5 years of working experience in construction project management followed by less than 2 years (16.4%) and 6-9 years (15.7%).

**Measures**

Scales in the questionnaire were provided for items representing the respondents’ opinion about value co-creation involving stakeholders, the project’s success, and stakeholder’s satisfaction of their companies. Multi-item scales were used to measure each construct in the study. All the constructs and measurements were valid and reliable because they have been used and tested by past scholars in the study area (Rojas, Liu, & Lu, 2018; Sahi, Sehgal, & Sharma, 2017; Zheng, 2017; Liu, & Lu, 2018)
We generated the questionnaire items by reviewing existing literature on value co-creation, project success, and stakeholders’ satisfaction. All the measures used in the study were adopted from previous studies.

**Value Co-creation (VCC)** was measured using nine items or criteria, each adapted from Rojas, Liu, and Lu (2018) and Sahi, Sehgal, and Sharma, (2017). For example, VCC1 “Host communities’ alignment/involvement throughout the project”. **Project Success (PS)** was measured using three items taken from Zheng (2017) and Sahi, Sehgal, and Sharma, (2017). **Project Stakeholder Satisfaction (PSS)** was measured with five items derived from Liu, and Lu, 2018); Sahi, Sehgal, and Sharma, (2017). For instance, for PSS1, one of the questions was “How do you rate the project sponsor’s satisfaction with the project’s deliverables?” All items were anchored with a seven-point Likert scale (7= Completely Agree and 1= Completely Disagree).

**Evaluation of the Measurement Model**

The most important measurement models used to evaluate the predictive capability of a study model are internal consistency (Cronbach’s Alpha and Composite Reliability), convergent validity (indicator reliability, Average Variance Extracted (AVE)) and discriminant validity (cross-loading and Heterotrait-heteromethod (HTMT)). The estimation results for the measurement model are presented in Tables 2 and 3. Cronbach’s Alpha and Composite Reliability were used to measure the reliability of the internal consistency. Results of the partial least squares structural equation modelling (PLS-SEM)
Algorithm report shows that all the values met the accepted value of 0.7 (Henseler, Ringle, and Sarstedt, 2015; Hair, Ringle, and Sarstedt, 2016; Nunally, 1978). Meeting the accepted value validated that the questions used to measure the constructs were reliable.

To evaluate the extent to which the measures of the same constructs positively correlated with each other, the outer loadings of the indicators and AVEs were calculated. Results of the PLS-SEM Algorithm revealed that all loadings (except loadings VCC4, PSC1, and PSS3) and AVEs are greater than the recommended threshold of 0.7 and 0.5, respectively. This suggested that an adequate convergent validity and fulfils all the acceptable criteria (Henseler, Ringle, and Sarstedt, 2015; Hair, Ringle, and Sarstedt, 2016; Bagozzi and Yi, 1988; Fornell and Larcker, 1981).

To test the construct’s uniqueness or the extent to which a construct is truly distinct from the other constructs, discriminant validity evaluation was used. Cross loading analysis (see Table 2) was also performed to test the discriminant validity, while the PLS-SEM Algorithm report showed that all the indicator’s outer loading on the associated construct was greater than all of its loadings on other constructs. Therefore, the cross-loading and discriminant validity criteria for PLS-SEM was fulfilled (Henseler, Ringle, and Sarstedt, 2015; Hair, Ringle, and Sarstedt, 2016; Chin, 2010; Fornell and Larcker, 1981).

Finally, we tested whether the HTMT values were significantly different from 1 (Henseler, Ringle, and Sarstedt, 2015), and the confidence internals bias-corrected results in the bootstrapping report showed that all numbers are
different from 1. The PLS-SEM Algorithm and bootstrapping reports of the SmartPLS analysis showed that the measures used were internally consistent, reliable and adequately valid.

Data Analysis

The relationships in Fig. 1 were analyzed using partial least squares structural equation modelling (PLS-SEM) and SmartPLS 3.2.2 software. PLS-SEM method was used instead of the traditional covariance-based technique (CB-SEM) because CB-SEM requires a large sample size (Kline, 2012; Henseler, Ringle, and Sarstedt, 2015; Hair, Ringle, and Sarstedt, 2016). In addition, the PLS-SEM method was preferred based on the objective to explain the variance (prediction of the constructs). The first step in applying the PLS-SEM method was the outer model’s validation and the second was the inner model path’s calculation.

Validating the outer model consisted of determining the convergent and discriminant validity as well as the reliability of the constructs (Henseler, Ringle, and Sarstedt, 2015; Hair, Ringle, and Sarstedt, 2013 and 2016). Once the model was validated, assessment of the PLS-SEM results of the inner model was fitted-in by calculating the path’s coefficients, collinearity, coefficients of determinants (R2 value), effect size (f2), blindfolding, predictive relevance (Q2), and effect size (q2). The significance of the results was demonstrated through bootstrapping. To examine the mediating effect of the project’s
success in the relationship between value co-creation and stakeholder’s satisfaction, the bootstrapping analysis was employed.

**FINDINGS**

**Assessing the Structural Model**

Results of the PLS-SEM structural model were assessed by examining the model’s predictive capabilities and relationships between the constructs. Firstly, a collinearity assessment was done to identify any potential collinearity of the indicators. The collinearity statistics indicated that values of the variance inflated factors (VIF) for value co-creation (1.000), project success (4.507), and stakeholder’s satisfaction (4.507) were below 5, demonstrating that there were no collinearity problems (Hair, Ringle, and Sarstedt, 2011 and 2016).

The next procedure of the PLS-SEM was determining the path coefficients, which is the coefficient linking of constructs in the structural model, and represents the hypothesized relationship or the strength of the relationship. Results of both the inner model path coefficients and the outer loadings are depicted in Fig. 2 below.
Assessing the structural model, bootstrapping was used to assess the significance of the path coefficients at a minimum number of bootstrap samples with 5,000 valid observations (Hair, Ringle, and Sarstedt, 2016). This helped to compute the empirical $t$ and $p$ values for all structural path coefficients. The SmartPLS bootstrapping report is summarized in Table 4 below.

**Path Coefficients and Direct Effects**

The results of path coefficients and direct effects shown in Table 4 below are used to examine H1 and H2.
**H1:** Value co-creation is positively related to construction project success.

**H2:** Value co-creation is positively related to a construction project’s stakeholder’s satisfaction.

*Table 4: A Summary of the Path Coefficient Estimates, t Values, and p Values*

Results of the bootstrapping analysis revealed that value co-creation is significantly, directly and positively related to the construction project’s success (path coefficients = 0.931, p < .05, and t < 1.96). This result supports H1 of the study. Furthermore, the study found that there is a significant positive and direct relationship between value co-creation and stakeholder’s satisfaction of the project (path coefficients = 0.672, p < .05, and t < 1.96). This result supports H2. These findings indicate that the impact value co-creation had on a project’s success is much stronger than the impact on stakeholder’s satisfaction.
Mediation (Indirect) Effect

Bootstrapping analysis was also performed to test the indirect effect identified in H3. Findings on H3 are presented in Table 5.

**H3:** A project’s success will mediate the relationship between value co-creation and stakeholder’s satisfaction.

The path analysis results revealed that a project’s success mediates the relationship between value co-creation and stakeholder’s satisfaction (path coefficients, $\beta = 0.258$, $p < .05$). The result supports the indirect effect of value co-creation on stakeholder’s satisfaction through the project’s success (H3). This type of mediation is called complementary mediation (Nitzl, Roldán, and Cepeda, 2016; Hair, Ringle, and Sarstedt, 2016), because both the indirect and direct effects are significant and point to the same direction.

**Table 5:** Indirect Effect (Mediation)

The Coefficient of Determination (R Square) and Effect Size $f^2$

The PLS-SEM Algorithm was calculated for the $R^2$ results and effect size $f^2$ (see Table 6). The coefficient of determination ($R^2$ value) shows the structural model’s predictive accuracy and is calculated as the squared correlation between a specific endogenous construct’s actual and predicted values.
(Hair et al., 2014). $R^2$ represents the amount of variance in the endogenous constructs explained by all the exogenous constructs linked to it (Hair et al., 2014).

The $R^2$ results revealed that an acceptable part of the constructs’ variance can be explained by the model ($R^2 = 0.867$, and $0.875$, for the PSC and PSS constructs, respectively). The $R^2$ value ranged from 0 to 1 and a value near 1 indicated a high predictive accuracy. These findings demonstrate that value co-creation can more substantially predict both the project’s success and stakeholder’s satisfaction (Hair et al., 2011; Henseler, Ringle, and Sarstedt, 2009; Chin, 1998). We also assessed the effect size ($f^2$) of each exogenous construct for its impact on the endogenous constructs. According to Cohen (1988), $f^2$ values of 0.02, 0.15, and 0.35, represent small, medium, and large effects, respectively, of the exogenous latent variable (Cohen, 1988). The results revealed that the effect size of all variables were large (>0.35).

**Blindfolding and Predictive Relevance ($Q^2$) and Effect Sizes ($q^2$)**

The final procedures of the PLS-SEM are the blindfolding, predictive relevance ($Q^2$) and effect size $f^2$ (see Table 7). While the $R$ square values denote
predictive accuracy, the Predictive Relevance ($Q^2$) indicates the model's predictive relevance, which is called “Stone-Geisser's $Q^2$ value” (Geisser, 1974; Stone, 1974). The $Q^2$ value was obtained by the blindfolding procedure for a specified omission Distance (D) with a value between 5 and 10 (Hair et al., 2016). $Q^2$ values larger than zero for a certain reflective endogenous latent variable indicates the path model's predictive relevance for the construct (Hair et al., 2014, pp 178).

The blindfolding analysis with omission Distance (D) value of 7, indicates that the $Q^2$ value is greater than zero (0.493) and shows that our path model's predictive relevance is high (Hair et al., 2014). Finally, Effect Size ($f^2$) was calculated with the formula $q^2 = (Q^2 \text{ included} - Q^2 \text{ excluded})/ (1 - Q^2 \text{ included})$, where $Q^2 \text{ included}$ and $Q^2 \text{ excluded}$ are the $Q^2$ values of the endogenous latent variable when a selected exogenous latent variable is included or excluded from the model, to assess an exogenous construct's contribution to an endogenous latent variable’s $Q^2$ value. The results show that the exogenous construct (value co-creation) has a large (0.741) predictive relevance for the endogenous construct (project success).

Table 7: The results of the Blindfolding and Predictive Relevance ($Q^2$) and Effect Sizes $q^2$
DISCUSSION

The research objectives are to identify the link between value co-creation and a project’s success and its stakeholder’s satisfaction, in addition to the mediating effect the success has on the relationship between value co-creation and stakeholder’s satisfaction. The results of the study revealed that there are high and substantial predictability and large predictive relevance between value co-creation and a project’s success. The findings imply that when project managers and project organizations involve project stakeholders throughout the project’s life span through collaboration, consultations, and stakeholder meetings, the likelihood of the project to be successful is high.

This finding is in line with the results of a study by Rojas, Liu, and Lu (2018), which validated that value co-creation relates significantly and positively to a project’s success and performance. Similarly, Corsaro (2018) and Savolainen et al. (2018) found that the adoption of a value co-creation approach in project management positively and directly influenced the success of the project. The findings also support Chang, Chih, Chew, and Pisarski’s (2013) study which concluded that the key to a project’s success is found in the value created and captured during and after projects, both for the funding organization as well as for the stakeholders.

Secondly, it was found that value co-creation had a significant positive and direct influence on a project’s stakeholder’s satisfaction. Additionally, value co-creation had a very strong and substantial predictability and large
predictive relevance for stakeholder’s satisfaction. The result implies that when the stakeholder is involved in value creation, their needs are met and they become satisfied with the project’s performance. This finding is consistent with the results of McHugh, Domegan, and Duane (2018), Savolainen et al. (2018), Sahi, Sehgal, and Sharma (2017), Keeys and Huemann (2017), Firend and Langroudi (2016), Grisseman and Stokburger-Sauer (2012), Lambert and Enz (2012) and Roggeveen, Tsiros and Grewal (2011).

McHugh, Domegan, and Duane (2018) and Savolainen et al. (2018) found a significant positive and direct correlation between value co-creation and stakeholder’s satisfaction. Similarly, Sahi, et al. (2017) revealed that value co-creation has a significant positive impact on customer satisfaction. Keeys and Huemann (2017) and Langroudi (2016) agreed that addressing stakeholder’s concerns towards value through value co-creation positively and directly influences the stakeholder’s satisfaction. Finally, Grisseman and Stokburger-Sauer (2012), Lambert and Enz (2012) and Roggeveen, et al (2011) found that the degree to which the stakeholders are involved in value co-creation positively influences the customer’s and stakeholder’s satisfaction with the firm.

Finally, the results of the indirect or mediating effect analyses indicated that value co-creation positively and indirectly influenced stakeholder’s satisfaction through the project’s success. The mediation effect analysis results indicated that there is a complementary mediation because both the
indirect and direct effects are significant and has the same direction (Nitzl, Roldán, and Cepeda, 2016; Hair, Ringle, and Sarstedt, 2016). The results also indicated that a project’s success has a greater effect size on stakeholder’s satisfaction than value co-creation. These findings suggest that involving stakeholders in the creation of value in project management will not necessarily make them satisfied, but rather until the project’s outcomes satisfies all its requirements. This is consistent with Markovic, and Bagherzadeh’s (2018) study which found that the breadth of the external stakeholder’s co-creation is not directly related to performance of the innovation. Furthermore, value co-creation with stakeholders aids the shaping of sustainable development of projects which ultimately creates stakeholder satisfaction (Keeys and Huemann, 2017).

**Research Implications**

This study fortifies several research implications in existing theories in value co-creation, previous project management researches and studies on stakeholder satisfaction. Even though there is an ever-growing body of literature that investigates value co-creation and satisfaction, fewer exists on value co-creation in the management of stakeholders of construction projects. This research is in response to fill this perceived gap in the extant literature, by investigating the linkages between value co-creation and a project’s success (schedule, budget, scope, and quality) and stakeholder’s satisfaction.
Majority of the studies in the past were conceptual (Haddadi et al, 2016) and qualitative in nature (Smyth and Vaesken, 2018), thus not exploring the cause-and-effect relationships in the context of construction project management. The empirical findings provide evidence of the influence of value co-creation on stakeholder satisfaction of projects through its success, (see Figure 3). Thus, the theoretical framework in Figure 3 provides a summary of how value co-creation influences the satisfaction of project stakeholders.

Figure 3. The theoretical framework on value co-creation and project stakeholders’ satisfaction

Managerial Implications

This study has some practical and managerial implications. The findings concluded that co-creating value with project stakeholders has a positive impact on the project’s success and stakeholder’s satisfaction. The adoption and implementation of value co-creation in project management enhanced the definition of the project’s scope, performance specifications, and other success criteria to meet the stakeholder’s needs. Also, when project firms and
managers co-create value with stakeholders, it eases the difficulties in changing the project’s scope when the need arises.

The adoption of the value co-creation approach in the management of projects should not undermine the success of the project; rather, it has to lead to its success. This study has confirmed that value co-creation impacts stakeholder’s satisfaction through the project’s success. This would mean that irrespective of the degree of a stakeholder’s involvement in the project’s value creation process, if it does not lead to success, clients, customers, team members, sponsors, and all other possible stakeholders will be dissatisfied. Based on this possibility, we suggest that project managers be critical of the type of value co-creation strategy they will use to engage project stakeholders, when adopting the value co-creation approach to manage their projects while not sacrificing success.

We second scholars who found that the value co-creation approach has a significant positive and direct impact on a project’s success. The current study adds to the value co-creation and project management literature with empirical evidence about the positive correlation between value co-creation and a project’s success and stakeholder satisfaction. Also, by making project success as a mediator, this paper lays a foundation for further theoretical explorations in value co-creation in project management. Finally, we conclude that the adoption of the value co-creation approach to project management has a significant positive direct, and indirect impact on stakeholder’s satisfaction.
Further Research Directions

This study focused on the impact of value co-creation on a project’s success and stakeholder’s satisfaction. The survey data were collected only for the overall effect of value-co-creation on the project’s success and stakeholder’s satisfaction. Therefore, we suggest that future studies on value co-creation in project management should also consider investigating the type of value co-creation strategy or approach that has a higher impact. In addition, we suggest further studies on the proposed model with a larger sample size from different countries and industries. Finally, we suggest that our model be further tested using the CB-SEM approach.
